PREFACE

Data and data summaries presented herein were collected during 1981 and compiled at the US Army Engineer Waterways Experiment Station (WES) Coastal Engineering Research Center's (CERC's) Field Research Facility (FRF) in Duck, N. C. This report is the third of a series of annual FRF data summaries carried out under CERC's Waves and Coastal Flooding Program.

The report was prepared by H. Carl Miller, oceanographer, under the supervision of Curt Mason, Chief, FRF Group, Research Division. William E. Grogg, Jr., electronics technician, assisted with instrumentation. J. Ross Rottier, oceanographer; Michael W. Leffler, civil engineering technician; and C. Ray Townsend III, amphibious vehicle operator, assisted with data collection and analysis. Drs. Robert W. Whalin and Lewis E. Link, Chief and Assistant Chief, respectively, of CERC, and Dr. James R. Houston, Chief, Research Division, provided general guidance.

In addition, a special thank you is extended to the National Oceanic and Atmospheric Administration (NOAA)/National Weather Service, who helped with the anemometer, and to NOAA/National Ocean Service, who maintained the tide gage and provided analysis results.

Commander and Director of WES during the publication of this report was COL Robert C. Lee, CE; Mr. F. R. Brown was Technical Director.

ANNUAL DATA SUMMARY FOR 1981
CERC FIELD RESEARCH FACILITY

PART I: INTRODUCTION

1. The US Army Engineer Waterways Experiment Station (WES) Coastal Engineering Research Center's (CERC's) Field Research Facility (FRF) located on 176 acres* at Duck, N. C. (Figure 1), consists of a 561-m-long research pier and an accompanying office building. The FRF is located near the middle of Currituck Spit along a 100-km unbroken stretch of shoreline extending south from Rudee Inlet in Virginia to Oregon Inlet, N. C. It is bordered by the Atlantic Ocean to the east and Currituck Sound to the west. The Facility is designed to (a) provide a rigid platform from which waves, currents, water levels, and bottom elevations can be measured, especially during severe storms; (b) provide CERC with field experience and data to complement laboratory and analytical studies and numerical models; (c) provide a manned field facility for testing new instrumentation; and (d) serve as a permanent field base of operations for physical and biological studies of the site and adjacent region.

2. The research pier is a reinforced concrete structure supported on 0.9-m-diam steel piles spaced 12.2 m apart along the pier length and 4.6 m apart across the width. The piles are embedded approximately 20 m below the ocean bottom. The pier deck is 6.1 m wide and extends from behind the dune line to about the 6-m water depth contour at a height of 7.8 m above National Geodetic Vertical Datum (NGVD). The pilings are protected against sand abrasion by concrete erosion collars and against corrosion by a cathodic system.

3. An FRF Measurements and Analysis (FRFMA) program has been established to collect basic oceanographic and meteorological data at the site, reduce and analyze these data, and publish the results.

4. This report is the third in a series of annual reports and summarizes the data collected during 1981. Data for 1977-1979 and 1980 are summarized in Miller 1982 and 1984, respectively. This report is organized such that descriptions of the instrumentation, including sensor calibration and maintenance (Part III) and data collection and analysis techniques (Part IV) precede reporting of the data (Part V). Appendixes A-D present, respectively,

* To convert acres to hectares, use a conversion factor of 0.40469.

Figure 1. Location of Field Research Facility

the following material: calibration and maintenance information for the Waverider buoy gages used to monitor waves; monthly and annual 1981 wave data; bathymetric contour diagrams and bottom elevation time histories for selected locations under the FRF pier; and meteorological and oceanographic data for 1981 storms. Although this is intended as a stand-alone document, details of some procedures and instrumentation are given in the references.

5. Future annual reports will have approximately the same format; readers' comments on the format and usefulness of the data presented are encouraged.

6. In addition to the annual reports, monthly data reports summarizing the same types of data shortly after the data are collected are available to requesters from the following address:

Chief
Field Research Facility
SR Box 271
Kitty Hawk, NC 27949

7. The CERC Coastal Engineering Information Analysis Center (CEIAC) is responsible for storing and disseminating most of the data presented or included to in this report. All data requests should be submitted in writing to:

Commander and Director
US Army Engineer Waterways Experiment Station
ATTN: CEIAC
PO Box 631
Vicksburg, Miss. 39180

Tidal data other than the summaries in this report should be obtained directly from the Tide Analysis Branch, National Ocean Service (NOS), Rockville, Md. 20850. A complete explanation of the exact data desired for specific dates or times will expedite filling any request; an explanation of how the data will be used will help CEIAC or NOS determine if other relevant data are available. For information regarding the availability of data, contact CEIAC at (601) 634-2017. Costs for collecting, copying, and mailing will be borne by the requester.

PART II: CLIMATOLOGICAL SUMMARY

Climate

8. The FRF enjoys a typical marine climate which moderates the extremes of both summer and winter. Average air temperatures in the coldest months, January and February, are near 5° C; during the warmest months, July and August, temperatures are near 27° C. Ocean water surface temperatures at the FRF tend to be lowest in February, averaging 4° C, and highest in September, with an average of 23° C. Because of this lag in the response of the ocean to temperature change, diurnal air temperature differences tend to be greatest in the late spring and fall.

9. Precipitation annually averages 1,009 mm and is generally well-distributed throughout the year. Frontal precipitation from midlatitude cyclones predominates in the winter, while local convection (thunderstorms) accounts for most of the summer rainfall.

10. Winds at the FRF have a distinctly seasonal distribution, being generally from the north and northeast in the fall and winter and from the southwest in the spring and summer. The occasional fall and winter storms (northeasters) can produce winds with average speeds of 15 m/sec or more. Besides these midlatitude storms, tropical cyclones (hurricanes) can enter the area. Although the portion of the North Carolina coast in the vicinity of the FRF experiences a fairly low occurrence of direct hurricane strikes (once every 42 years), more frequent near-misses can cause high wave conditions at the FRF.

Waves

11. Wave directions at the FRF, as with winds, are seasonally distributed. Waves are predominantly from the northeast in the fall and winter and approach from the southeast in the spring and summer.

12. The annual mean wave height (measured at the seaward end of the FRF pier) is 0.9 m, with a standard deviation of 0.6 m. Wave heights are generally smallest in spring and summer and greatest in fall and winter.

13. Wave periods vary throughout the year between about 5 and 16 sec, with an annual mean peak spectral period of 8.7 sec and a standard deviation of 2.9 sec.

Nearshore Currents

14. Longshore currents inside the breaker line are associated in direction and strength with wave height and direction, being generally strongest and to the south (though with frequent reversals) in fall and winter and more predominantly to the north in spring and summer.

15. Rip currents occur frequently in the area, especially at cuts in the offshore sandbar, such as the one underneath the pier.

Tides and Water Level Changes

16. Ocean tides at the FRF occur semidiurnally, with a mean range of 1.0 m. Local mean sea level (MSL) since 1978 has been 8 cm above the 1929 NGVD. Water levels in Currituck Sound are wind-dominated rather than tidal, being low when winds are northeasterly and high when they are southwesterly.

Sediment Size

17. Offshore material decreases in mean grain size and becomes increasingly well sorted with distance from shore. Mean sizes vary from 0.4 mm (1.31 phi) near the shore to 0.12 mm (3.11 phi) at the 15-m-depth contour, about 2,000 m offshore.

18. Mean grain size of beach sand decreases from 0.52 mm (0.9 phi) at the mean low water (MLW) line to 0.38 mm (1.4 phi) at the dune. The sediment has a bimodal distribution of coarse material mixed with much finer sands. Mean foreshore sand sizes are smallest in the summer when wave energies are lowest.

Bathymetry

19. Nearshore bathymetry at the FRF is characterized by regular shore-parallel contours, a moderate slope, and two bars, with a wide outer bar and a well defined inner bar. This pattern is interrupted in the immediate vicinity of the pier by a shallow trough which runs the length of the pier, ending in a scour hole under the seaward end of the pier which measures up to 3.0 m deeper than the adjacent bottom.

PART III: INSTRUMENTATION

20. This section identifies the instruments used for long-term monitoring of oceanographic and meteorological conditions and briefly describes their design, operation, and location. More detailed explanations can be found in Miller (1980). Equipment (i.e., the surveying system) used for collecting other types of data is discussed in Part IV.

Wave Gages

Baylor wave staff gages

21. Two parallel cable inductance wave gages, manufactured by the Baylor Company, Houston, Tex., were mounted on the FRF pier, one at sta 6+20 and one at 19+00 (Figure 2). These rugged and reliable gages required little maintenance except to keep tension on the cables and to remove any material which could have caused an electrical short circuit between the cables. They were calibrated prior to installation by placing an electrical short between the two cables at known distances along the cables and noting the voltage output. In the field, electronic signal conditioning amplifiers were used to ensure that the output signals from the gages were within a 0- to 5-V range. Gage accuracy was about 1 percent, with a 0.1 percent full-scale resolution. These gages were susceptible to lightning damage, but protective measures have been taken to minimize such occurrences.

Waverider buoy wave gages

22. Two Waverider buoy gages were positioned 0.6 and 3 km offshore at the FRF (Figure 2). These gages, manufactured by the Datawell Laboratory for Instrumentation, Haarlem, Netherlands, measured the vertical acceleration produced by the passage of a wave. The signal was doubly integrated to produce a displacement signal, which was transmitted by radio to an onshore receiver. The manufacturer stated that wave amplitudes are correct to within 3 percent of their actual value for wave frequencies between 0.065 and 0.5 Hz (15- to 2-sec wave periods); however, calibration curves for buoys used at the FRF indicated that the wave heights reported in Part V of this report for wave periods less than 15 sec averaged about 5 percent less than actual values. For wave periods greater than 15 sec, this error was appreciably more, although waves of this type occurred less than 1 percent of the time at the

Figure 2. FRF instrumentation locations

FRF. For most engineering applications, a 5 percent error may be acceptable, but a correction procedure described in Appendix A will reduce such errors to 4 percent or less.

Tide Gages

23. Water level data were obtained from a National Oceanic and Atmospheric Administration (NOAA)/NOS control station (No. 865-1370) located at the seaward end of the research pier, using a digital tide gage manufactured by Leupold and Stevens, Inc., Beaverton, Oreg. The Leupold-Stevens analog-to-digital recorder, a float-activated, negator-spring, counterpoised instrument, mechanically converted the vertical motion of a float into a coded, punched paper tape record. The below-deck installation at pier sta 19+60 (Figure 2) consisted of a 30.5-cm-diam stilling well with a 2.5-cm orifice and a 21.6-cm-diam float.

24. This tide gage was checked daily for proper operation of the punch mechanism and accuracy of the time and water level information. The accuracy was determined by comparing the gage level reading to a level read from a reference electric tape gage. Once a week, a heavy metal rod was lowered down the stilling well and through the orifice to ensure free flow of water into the well. During the summer months, when biological growth was most severe, divers inspected and cleaned the orifice opening as required.

25. Quarterly, a NOAA/NOS tide "party," which consisted of NOS personnel familiar with the installation and equipment, performed a tide station inspection and review. The tide gage was surveyed in from existing NOS control positions, and the equipment was checked and adjusted as needed. NOS and FRF personnel reviewed procedures for tending the gage and handling the data. Any specific comments on the previous months of data were discussed to ensure data accuracy.

Meteorological Instruments

Anemometer

26. Winds were measured using a Weather Service Model F420C anemometer consisting of a cup rotor and spread-tail wind vane located on the top of the laboratory building at an elevation of 19.1 m (Figure 2). The accuracy of the

speed transmitter and indicator assemblies was (a) 1 percent up to 100 m/sec and (b) 2 percent over 100 m/sec. The wind direction transmitter and indicator assemblies were accurate to ± 5 deg at an airspeed of 0.26 m/sec or greater.

27. In April, NOAA/National Weather Service (NWS) personnel calibrated the speed cups and verified that the direction was referenced to true north. The speeds were found to be approximately 13 percent (linear) faster than actual, and the instrument was reset. Generally, speeds lower than the manufacturer's specifications for this anemometer are due to deterioration of bearings; however, speeds found faster than specified usually are due to an accidental shift of the chart recorder calibration. The chart calibration is controlled by a lever which could easily have been bumped when chart paper was changed at the end of the month. It is suggested that the data reported here be scaled lower by 13 percent for January through 23 April.

28. The wind speed and direction were recorded on a battery-powered Esterline-Angus recorder. Problems with the recorder's clock and tape-advance mechanism and the pen actuator (for indicating direction) were frequently found, and the unit required day-to-day maintenance. Maintenance of the anemometers consisted of troubleshooting the recorders and resetting the instrument based on the calibration results.

Microbarograph

29. This recording instrument, an aneroid sensor used to measure atmospheric pressure, responded to pressure changes on the order of 0.169 mb. The microbarograph, manufactured by the Belfort Instrument Company, Baltimore, Md., was located inside the laboratory building, 9 m above NGVD (Figure 2).

30. The microbarograph was compared to an NWS aneroid barometer daily; infrequent adjustments were made as necessary. The microbarograph required very little maintenance except that required to ink the pen and wind the clock every 3 days when the chart paper was changed.

Maximum/Minimum thermometers

31. NWS maximum and minimum thermometers were used to determine the daily extreme air temperatures. The thermometers were housed in an NWS instrument shelter located 43 m behind the dune (Figure 2). The shelter was designed with louvered sides, a double roof, and a slatted bottom for housing instruments requiring protection from direct sunlight.

32. The actual temperature readings at the time the thermometers were read (i.e., the present temperature) were compared to ensure accuracy of

maximum and minimum values. Maintenance consisted of periodically removing and cleaning the thermometers with soap and clean water and lubricating the Townsend support used to hold and reset the instruments.

Rain Gage

33. A 30-cm weighing rain gage manufactured by the Belfort Instrument Company, Baltimore, Md., used to measure the daily amount of precipitation, was located near the instrument shelter 46 m behind the dune (Figure 2). The manufacturer's specifications indicated that the instrument accuracy was ± 0.5 percent for precipitation amounts less than 15 cm and ± 1.0 percent for amounts above 15 cm.

34. A 15-cm-capacity "true check" clear plastic rain gage with a 0.025-cm resolution, manufactured by the Edwards Manufacturing Company, Alberta Lea, Minn., was used to monitor the performance of the weighing rain gage. This gage, located near the weighing gage, was checked daily, and very few discrepancies were identified throughout the year. The weighing rain gage required little maintenance except to wind the clock and ink the pen.

Sling psychrometer

35. A sling psychrometer was used to measure wet and dry bulb temperatures for determining relative humidity and dew point. The psychrometer consisted of two thermometers mounted in a frame; a moistened muslin wick was attached to the bulb (i.e. wet bulb) of one of the thermometers, and the device was whirled to ventilate both thermometers. After the wet and dry bulb temperatures were read, a set of NWS tables was used to determine the dew point.

36. These thermometers required little maintenance except that required to change the muslin wick every month or two and to clean the sling and thermometers with soap and water. The instruments were not calibrated, but the thermometers were compared daily to detect any bias or malfunction.

Pyranograph

37. A mechanical pyranograph, manufactured by the Weather Measure Corporation, Sacramento, Calif., was located on top of the weather instrument shelter and provided a record of the duration and intensity of solar radiation. The pyranograph was not calibrated but was observed to operate in a reasonable manner. This equipment required that the glass cover be cleaned, the chart paper changed every week, the timer wound, and the pen inked.

PART IV: DATA COLLECTION AND ANALYSIS TECHNIQUES

38. In this section, the FRF data acquisition system, data collection techniques, and data analysis procedures are discussed.

Digital Wave Data

Data acquisition system

39. The data acquisition system consisted of primary and backup data collection equipment and associated electronics for signal conditioning prior to recording. The primary system was a Data General NOVA-4 minicomputer located in the FRF laboratory building. The backup system consisted of a Lockheed Store 7 (FM) recorder which was used infrequently to record data when the primary system was not operational. During storm conditions, the backup system was run simultaneously with the primary system to ensure that wave data were obtained. Each wave gage signal was first amplified and biased to ensure a 0- to 5-V range and then input to the collection equipment. However, since the backup FM recorder operates on a maximum output of 3 V, the signal was linearly scaled by a factor of 3/5.

Collection

40. The signals from the wave gages were routinely sampled four times per second for 20 min every 6 hr beginning as near as possible to 0100, 0700, 1300, and 1900 hours Eastern Standard Time (EST); these hours corresponded to the times that the NWS created daily synoptic weather maps. During storms, hourly data recordings were made.

Data tapes

41. The wave data were recorded in digital form on 9-track tapes with the following basic tape file format: two records of header information which include (a) the station identification number; (b) the date and time; and (c) calibration and signal bias factors followed by 13 records of data for each 20-min recording interval. Each record contained 384 20-bit integer words (i.e. binary format); each integer word represented the computer units corresponding to the instantaneous voltage output of the sensor. The above sequence of 15 records per file was repeated for each sensor and recording interval, until the data tape was filled, for a total of 600 to 700 files. The 20-bit word size is unusual but was necessary because CERC processed the

data on a CDC 6600 machine with a 60-bit word size; when necessary, CERC converted the data tapes to an ASCII format.

Analysis/Summarization procedures

42. The CERC procedure for analyzing and summarizing digital wave data was based on a Fast-Fourier Transform (FFT) spectral analysis procedure. The final results were subjected to human editing and quality control before public distribution (Thompson 1977; Harris 1974). The computer analysis routine used 4,096 data points (1,024 sec of data sampled four times per sec) for each data file processed.

43. The program computed an initial distribution of the data along with the first 5 moments of the distribution function and then edited the digital data file, checking for data points out of the 0- to 5-V range, "jumps," and "spikes." A jump is defined as a data value in excess of 2.5 standard deviations from the previous data point, while a spike is a data point 5 standard deviations or more from the mean. If fewer than 5 jumps, spikes, or points out of range, in a row, were found, the program linearly interpolated between acceptable data and replaced the erroneous data points. If either more than 5 in a row or a total of 100 bad data points for the file were found, the program (a) stopped interpolation and further editing, (b) analyzed the data, and (c) printed a flag indicating there was a problem with this data file. A variance of less than 0.001 sq m indicated that the waves were calm; therefore the record was not analyzed.

44. After editing, the distribution function and first 5 moments of the sea surface elevations were again computed. A cosine bell data window was applied to increase the resolution for the energy spectrum of the file (use of the data window is discussed by Harris (1974)). After application of the data window, the program computed the variance spectrum (energy spectrum) using an FFT procedure.

45. The symbols H_m (defined as four times the standard deviation of the sea surface elevation)⁰ and T_p (defined as that period associated with the maximum energy density in the spectrum (Thompson 1977)) provided a convenient way to characterize the wave conditions contained in the data file; they were more conducive to statistical summarization than the more complete, but complex, description provided by the spectrum.

46. After the data files were analyzed, the results were eliminated for files that were flagged as bad or that appeared inconsistent with

simultaneous observations from nearby gage sites. Frequently, the spectrum and/or distribution function of sea surface elevations were examined to determine if the data were acceptable. After the analysis results had been edited, monthly summaries of H_m and T_p were generated for inclusion in summary reports.

Tide and Water Level Data

Collection

47. The tide and water level information was obtained from an NOS tide gage which produced a digital paper tape of instantaneous water levels sampled continuously at 6-min intervals. At the end of each month, the paper tape was removed from the recorder and mailed to NOS in Rockville, Md., for analysis.

Analysis

48. The digital paper tape records of tide heights taken every 6 min were analyzed by the Tides Analysis Branch of NOS. A Mitron interpreter created a digital magnetic computer tape from the punched paper tape. This magnetic tape was then processed on a Univac 732 computer in the following manner. First, a listing of the instantaneous tidal height values was obtained for manual checking. If errors were encountered, a computer program was used to fill in or recreate bad or missing data, using correct values from the nearest tide station and accounting for known time lags and elevation anomalies. The data were plotted, and a new listing was generated and rechecked. When the validity of the data had been confirmed, monthly tabulations of daily highs and lows, hourly heights (instantaneous height selected on the hour), and various extreme and/or mean water level statistics were generated. The MSL reported here is the average of the hourly heights throughout the month, while the mean tide level (MTL) is midway between mean high water (MHW) and MLW.

Meteorological Data

Collection

49. Each instrument used for monitoring the meteorological conditions at the FRF was read and inspected daily. For those instruments with analog chart recording capabilities the following steps were taken: (a) the pen was

zeroed (where applicable); (b) the chart time was checked and corrected, if necessary; (c) a daily reading was marked on the chart for reference; (d) the starting and ending chart times were recorded, as necessary; and (e) new charts were installed when needed. Sample chart records for the microbarograph (atmospheric pressure), rain gage, and pyranograph (solar radiation) are presented in Figure 3. The daily reading was recorded for all instruments except the pyranograph. As the instruments were read, weather information such as cloud cover, visibility, and predominant weather conditions were visually obtained. Note that the cloud cover, visibility, dew point and atmospheric pressure summaries presented in Part V were prepared from single daily observations made near 0700 EST and thus do not represent daily or hourly averages; therefore, caution should be exercised when interpreting the results.

50. The wind data provided in this report were based on wind speed and direction values determined every 6 hr from the instrument chart records and represent estimated average values based on 10 min of record.

Analysis

51. Wind roses were computed for the wind speed and direction values obtained every 6 hr. The directions were specified at 22.5-deg intervals, i.e., at 16-point-compass-direction specifications. Frequency distributions (wind roses) of wind speed for each direction were computed for the entire year, each 3-month season, and monthly. Resultant directions and speeds were determined also by vector-averaging the data.

52. Dew-point values reported on herein were determined from psychrometer readings by computing the wet-bulb temperature depression (dry bulb minus wet bulb) and by using Table 19 in Appendix III of the Weather Service Observing Handbook No. 1--Marine Surface Observations (NOAA/NWS 1979).

Visual Observations

53. At the FRF, daily visual observations were made near 0700 hours to supplement instrumented data collection. These included observations of surface current speed and direction at (a) the seaward end of the pier, (b) the midsurf position on the pier, and (c) on the beach 500 m updrift of the pier. Also measured were the wave approach angle at the seaward end of the pier and the breaker angle and type nearshore.

b. Rain gage

c. Pyranograph

Figure 3. Sample chart records for the microbarograph, rain gage, and pyranograph

Bathymetric and Pier Surveys

Collection

54. Beginning in July, a series of profiles was obtained monthly using the Coastal Research Amphibious Buggy (CRAB), a 12-m-tall amphibious tripod, and a Zeiss Elta-2 total station surveying system. Detailed characteristics of this system are presented in Birkemeier and Mason (1984). Each profile extended seaward from the baseline behind the dune to a water depth of about 10 m, and profiles were located up to 0.6 km north and south of the FRF pier. The profile lines surveyed are located and identified on each contour diagram in Appendix C. The accuracy of these surveys was about ± 3 cm horizontally and vertically. Weekly soundings along both sides of the FRF pier were performed by means of a lead line surveying technique consisting of lowering a weighted measuring tape and noting the distance below the pier deck, a known elevation above NGVD. Positions between the pier bents (i.e., every 12.2 m) were used to minimize inaccuracies due to scour near the pilings.

Analysis

55. The pier, beach, nearshore, and offshore data were reduced to position (X,Y) and depth (Z) triplets relative to the local NGVD. The data were listed, and a display of the profiles (i.e., distance along the range versus elevation) using line printer graphics was generated for visual inspection. After the data had been edited and determined acceptable, another set of routines was used to compute contour diagrams of the bottom topography and time sequences of bottom elevations at selected locations along the pier.

Sediment Data

Collection

56. Sediment data were not collected routinely at the FRF during the year. Coincident with an experiment in the fall, personnel from CERC, the US Geological Survey (USGS) in Reston, Va., and Skidaway Institute of Oceanography in Georgia, collected grab samples and box cores from the ocean, beach, and nearshore and vibracores from the sound, across the island to the ocean. The grab samples were obtained with a clam shell grab and contain samples from approximately the top 10 cm of sediment.

Analysis

57. The sediment samples were sieve-analyzed to determine the size distribution of the samples. The sieves were at $1/2$ -phi intervals ($\phi = \log_2$ sediment diameter (mm)). This report presents a summary of the texture analysis.

Photographic Data

Aerial

58. Quarterly aerial photographic missions were performed by a contractor using a 9-in.-negative-format mapping aerial camera capable of black-and-white and color photography. All coverage was at least 60 percent overlap, with all flights flown as close as possible to periods of low tide between 1000 and 1400 hours, with less than 10 percent cloud cover.

59. The flight lines were concentrated near the FRF, although one flight line extended from Cape Henry, Va., to Cape Hatteras, N. C. The flight lines and scale specifications are shown in Figure 4.

Beach

60. As part of the visual observations, 35mm color slides of the beach were taken daily from the pier looking toward both north and south. The location from which each picture was taken, date, time, and a brief description of the picture were marked on the slides, and an inventory was maintained.

Analysis

61. There was no routine analysis of the photographic data except to inventory what was obtained.

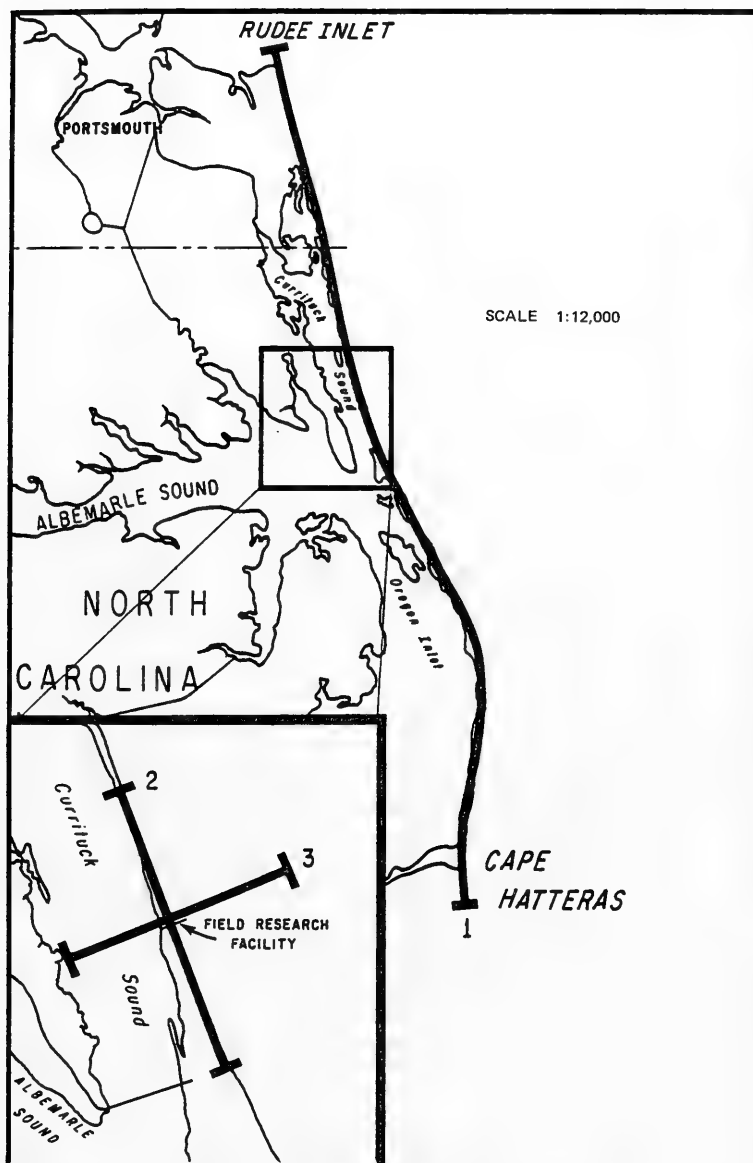

Figure 4. Quarterly aerial photography flight lines, 1981

PART V: DATA AVAILABILITY AND RESULTS

62. This part provides results of the weather, wave, surface current, tidal, water characteristic, survey, sediment, and photographic measurements made during the year. Table 1 is intended as a quick reference guide to show the dates for which various types of data are available. Wave gage histories which may explain major gaps in the data are provided in Appendix B. Although this report is intended to provide basic data for analysis by users, many of the daily observations have been summarized by month, season, and year to aid in interpretation. If individual data are needed, the user can obtain the detailed information by following the procedures described in paragraphs 6 and 7.

Meteorological Data

63. Table 2 summarizes monthly averages of the following daily measurements: cloud cover, visibility, dew point, and atmospheric pressure. Results of air temperature, precipitation, and wind speed and direction measurements for 1981, as well as prior years, are presented below. Appendix D contains hourly atmospheric pressure, wind speed, and wind direction data collected during storm conditions for 1981.

Air temperature

64. Air temperature measurements are summarized herein using the daily highest and lowest temperatures measured by maximum and minimum thermometers. Daily average temperatures are unobtainable since only one observation per day was made. The warmest months at the FRF in 1981 were June through September; the coolest months were typically January and February (see Table 2 and Figure 5. Monthly average daily high and low temperatures for 1981 were very similar to those for 1980. Annual average daily high temperature was 20° C, less than 1° C higher than for 1980. Annual average daily low temperature for both years was 11° C. As it was for 1980, the monthly range of temperatures for 1981 was the smallest during the warm summer months and as large as 31° C in February and December. These tendencies reflect the complex interaction of (a) ocean, whose temperature varies slowly, (b) winds, whose direction and speed can change very quickly, and (c) large airmasses, which can

Figure 5. Monthly high and low air temperatures

come from the north, with temperatures influenced by Arctic conditions, or from the south, where tropical influences prevail. Table 3 shows the monthly extreme temperatures since 1978. Five months of 1981, including the spring (April through June), showed the highest temperatures recorded since March 1978; likewise, four months, including September, October, and December, showed the lowest temperature recorded. The average date for the first occurrence of a freezing temperature was 30 November (21 November for the past 3 years), while the average date of the last occurrence was 13 March.

Precipitation

65. Unusually high precipitation during July, August, and December (Table 4) balanced an otherwise dry year, resulting in a near-normal annual total; monthly minima for the 1978-1981 period occurred six times during 1981 (Table 4). On 20 August, 115 mm of precipitation was recorded in a 24-hr period as the result of Tropical Storm Dennis (Figure 3).

Wind

66. Since local winds frequently control nearshore currents and wave conditions, an understanding of the wind and wave climates at any coastal

location is important to most studies of hydrodynamic and sedimentary processes. In this section, wind characteristics at the FRF are discussed based on measurements made four times per day during 1980 and 1981. Over these 2 years, the annual distribution of wind speeds and directions at the FRF showed a consistent pattern. The winds blew onshore from the north side of the pier more often (32 percent) than from the south (14 percent) (Figure 6). Winds blowing from the north side of the pier--i.e., north through east-northeast--produced onshore waves and southerly directed surface currents, while winds from the south side--i.e., east through south-southeast--produced onshore waves and northerly directed surface currents. Over 53 percent of the time, winds were directed offshore and did not produce waves onshore.

67. The strongest winds during 1980 and 1981 tended to blow from the north-northeast during January through March (Figure 7). High speeds and frequent northerly directions during October through December and January

through March resulted from Arctic and polar high-pressure systems (clockwise circulation), as well as extratropical and tropical cyclones (low-pressure systems with counterclockwise circulation). Winds originating as continental or Canadian air masses generally move east across the US, producing initially western and finally northern/northeasterly winds along the Atlantic coast; extratropical "northeaster" storms associated with low-pressure systems tend to move north along this coast, producing strong northeasterly winds followed by winds from the northwest.

68. Wind roses (Figure 7) for the spring and summer seasons, April through September, of combined 1980 and 1981 data, showed the strong influence of the tropical maritime airmass which produces winds that blow from the southwesterly direction. The resultant wind speed and direction vectors (Table 5) show an approximate balance of speeds and directions during July

Table 5

through September. In January through March and October through December for combined years, the northerly direction dominated; and the magnitudes were the greatest. The strongest southerly winds occurred in April through June. As mentioned, annual wind patterns were consistent from year to year (Figure 6). The seasonal variation shown in Figure 8 for 1981 changed from southerly in the warm months to northerly in the cold with an overall western dominance as is typical; however, as Figure 9 shows, monthly patterns can vary significantly. In January 1981, the wind blew from the west and from the southwest much more frequently than during 1980. The frequency of winds from north through northeast was approximately the same between the years for January, but winds were much more unidirectional from the north in 1981. For 28 percent of the time during February 1981, the winds blew from the southeast, while this occurred for only 13 percent of the time during February 1980; February 1981 was the month during 1980-1981 for which winds from the southeast were most frequently observed. During July 1981, the winds were more evenly distributed than during July 1980. Other months throughout the year showed only minor differences. Monthly wind roses for the combined years 1980 plus 1981 and 1981 alone are shown in Figures 10 and 11, respectively.

Wave Data

69. This section presents summaries of the wave data collected at the FRF during 1981. Annual and seasonal statistical summaries given below show a temporal and spatial variability of the wave climate at the FRF. Appendix B contains summaries for each gage which include statistics for 1980 and 1981 data combined, wave roses, persistence tables, and sample storm spectra for dates when H_{m0} exceeded 2.0 m at the seaward end of the FRF pier. Appendix D contains hourly wave data summaries for the storm dates in 1981.

Wave height

70. 1981 wave statistics (see tabulation below) vary as a function of gage installation: generally, as water depth (and distance from shore) increases so does the average annual H_{m0} value.

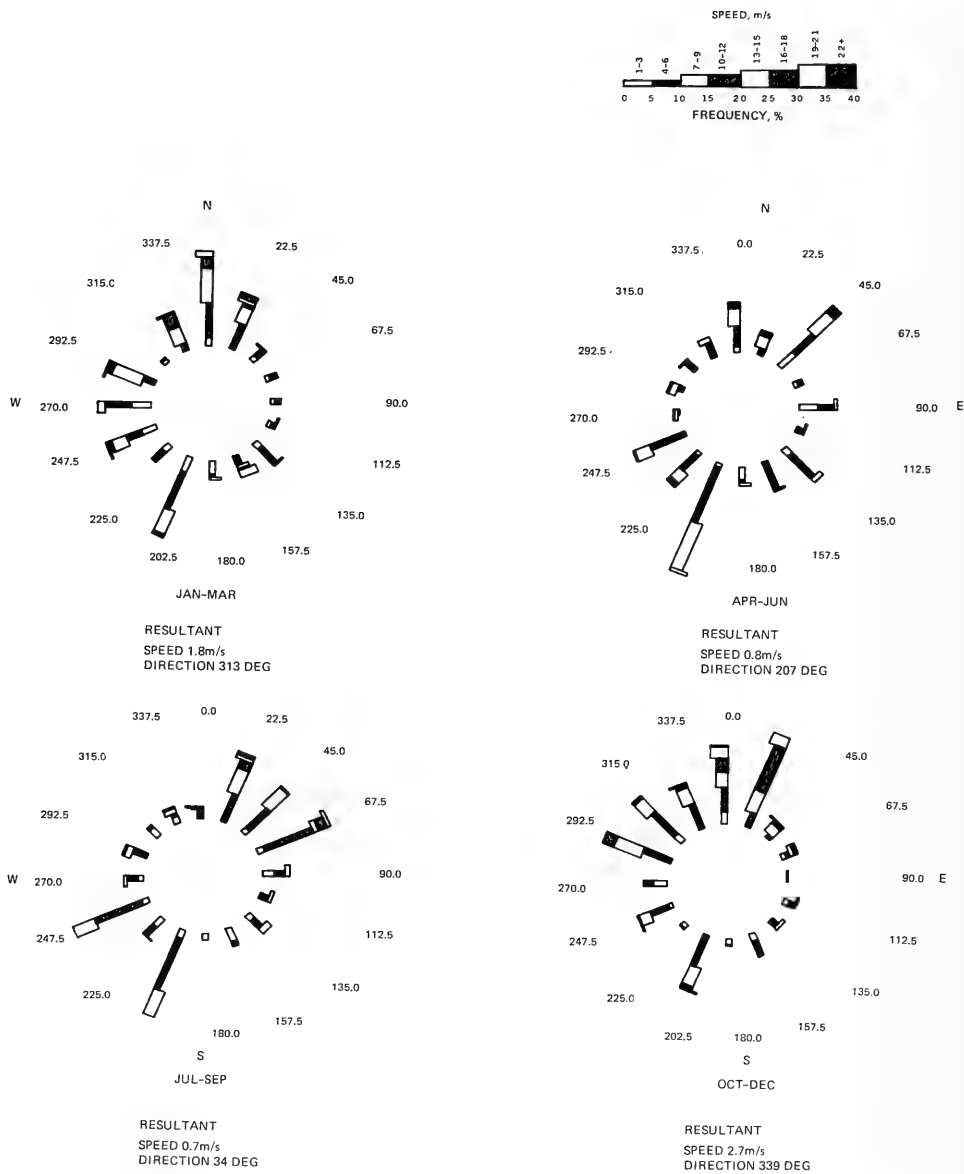

Figure 8. 1981 seasonal wind roses for FRF, reference true north

Figure 9. Wind roses for January, February, and July 1981 and 1980, reference true north

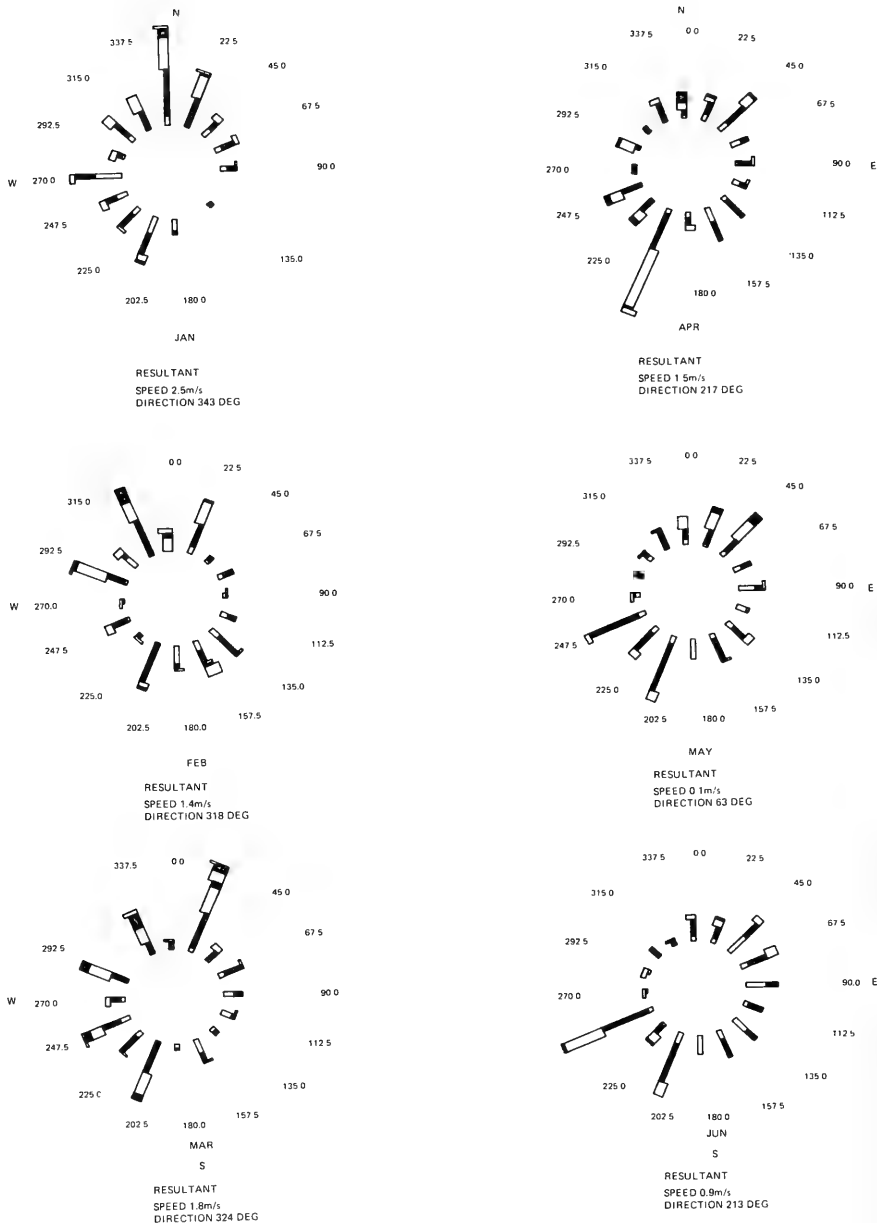

Figure 10. 1981 plus 1980 monthly wind roses for FRF, reference true north (Continued)

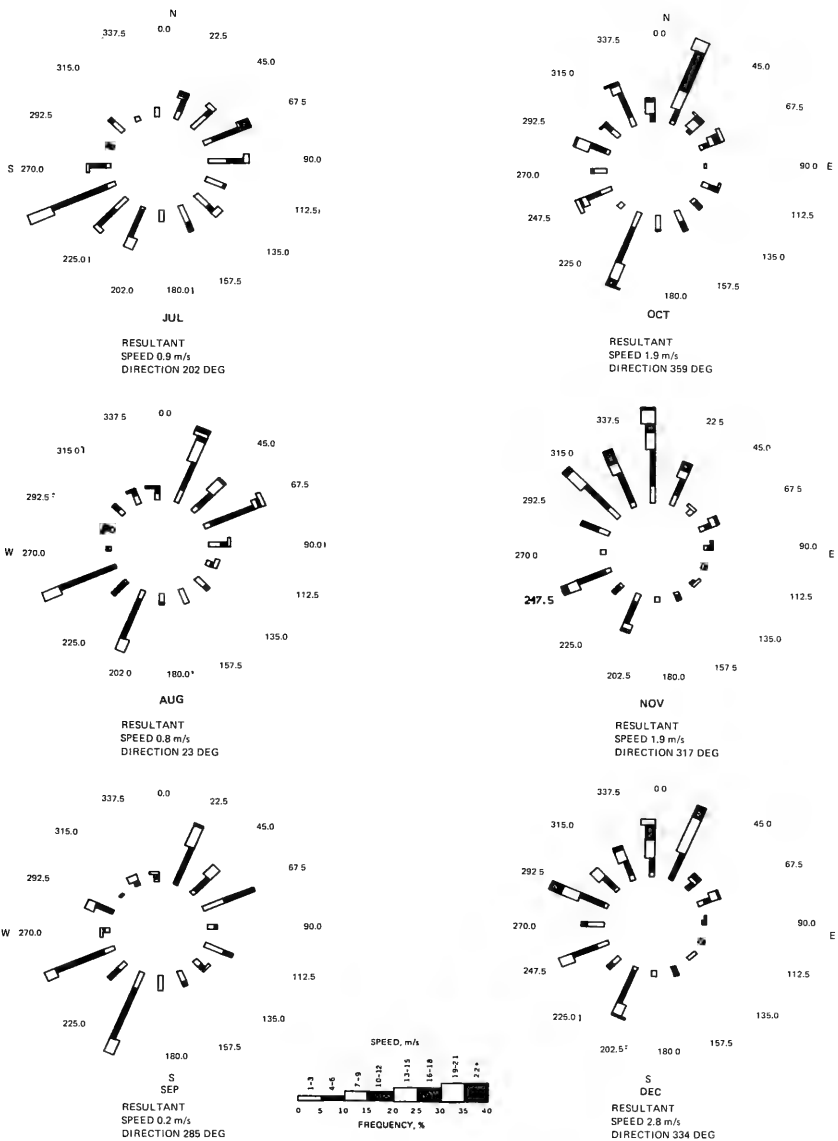

Figure 10. (Concluded)

Figure 11. 1981 monthly wind roses for FRF,
reference true north (Continued)

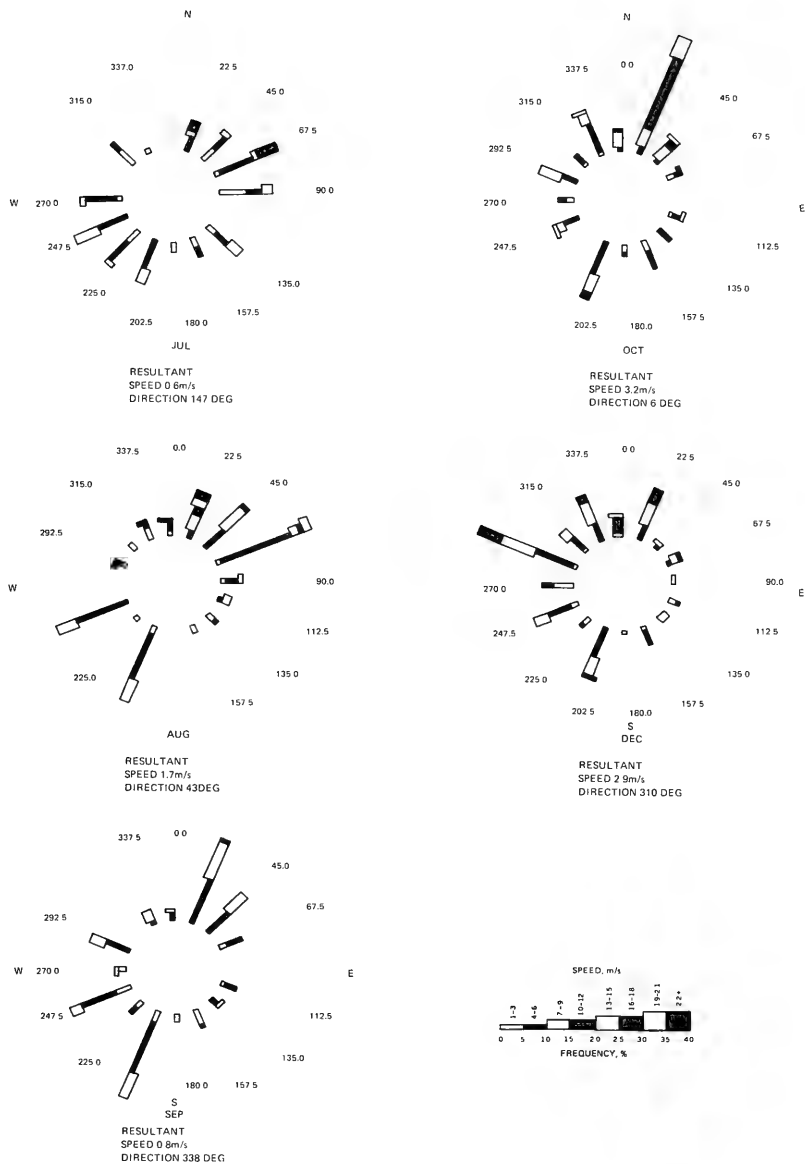

Figure 11. (Concluded)

| Gage | Distance from Shore, m | Average Annual Water Depth, m | H_{m_o} | | T_p | |
|----------------------------------|------------------------------|-------------------------------------|-----------|---------------|-------|-----------------|
| | | | Mean | Std Dev, m | Mean | Std Dev, sec |
| Nearshore Baylor (No. 615) | 100 | 2 | 0.7 | (0.3) | 7.9 | (3.1) |
| Pier End Baylor (No. 625) | 500 | 8 | 1.0 | (0.6) | 8.4 | (2.8) |
| Nearshore Waverider (No. 610) | 600 | 7 | 0.9 | (0.6) | 8.5 | (2.8) |
| Offshore Waverider (No. 620) | 3,000 | 18 | 1.0 | (0.6) | 8.0 | (2.8) |

71. Although the annual H_{m_o} values for gages 625 and 620 are the same, the distribution of H_{m_o} shows a greater frequency of large waves at the offshore gage location (Figure 12). The nearshore Baylor gage was in shallow water inside the breaker zone, even during moderate-to-low wave conditions; consequently, its statistics represent a lower energy wave climate frequently due to waves breaking seaward of the gage.

72. Wave conditions during the year varied with season. During October through December, wave heights were most severe, followed by July through

Figure 12. 1981 annual wave height distributions for all FRF gages

September and January through March; during April through June, the least severe conditions occurred (Figure 13).

73. The overall wave climate during 1981 was more severe than during 1980 (Figure 14). At gage 625 near the seaward end of the pier, 7 percent of the wave heights exceeded 2 m during 1981, while less than 5 percent did during 1980. Seasonal variation also differed from 1980. The much greater frequency of higher waves in August (Figure 15) and a succession of storms in September 1981 resulted in a much more severe summer (July through September) than 1980 (Figure 16). A mild January in 1981 was the primary reason the winter season (January through March) was less severe than the winter of 1980. These two seasons were thus reversed between years in order of severity.

74. The extreme H_m at the seaward end of the pier for 1981 was 3.5 m, which occurred in November during an extratropical northeaster storm (see Appendix D for storm data). This matched the 1980 extreme.

Wave period

75. Annual wave period distributions were consistent from gage to gage (Figure 17). The 1981 annual average wave period at the seaward end of the pier (gage 625) was 8.4 sec, with an associated 2.8-sec standard deviation (see tabulation, paragraph 70). Figure 18 shows the 1981 wave period

Figure 13. 1981 seasonal wave height distributions for gage 625

Figure 16. 1981, 1980, and 1981 plus 1980 July-September wave height distributions for gage 625

Figure 17. 1981 annual wave period distributions for all FRF gages

Figure 18. 1981 and 1980 wave period distributions for gage 625

distribution for gage 625. The most frequently occurring periods were 6, 8, and 10 sec (see Table 6). During storms when H_{m_0} was greater than 2 m, the periods ranged from 6 to 17 sec, although most were between 6 and 12 sec. This variation can in general be attributed to the distance of the wave-generation area from the pier; i.e., storms far offshore, say 500 km or more, tend to produce 12-sec or longer wave periods, while more local storms produce shorter periods. Based on the occurrence of periods longer than 10 sec, swell from distant generating areas may have accounted for approximately 20 percent of the conditions at the coast. During October through December, 6 sec wave periods occurred most frequently, while during April through June more than 30 percent of the wave periods were 8 sec (Figure 19).

76. With the exception of July through September, wave period distributions were consistent between 1980 and 1981. January through March tended to have longer (greater than 8 sec) periods, while during October through December, 6-sec locally generated seas predominated. A large difference was observed during July through September, when there were fewer 8-sec and more wave periods greater than 10 sec (Figure 20).

Figure 19. 1981 seasonal distribution of wave periods for gage 625

Figure 21. 1981 annual and seasonal wave roses at seaward end of FRF pier, reference true north

79. January through March and October through December were seasons with waves predominantly from the north (Figure 21). Waves approached from the south from April through September; over 70 percent of waves approached from the south during April through June.

80. As shown by the wind roses in Figures 6 and 8 and the wave roses in Figure 21, seasonal trends and the overall distribution of wave directions agree with trends in the wind climate at the FRF. In particular, an increase or decrease in northerly winds was the primary factor affecting the distribution of northerly wave directions during the year. This suggests northerly waves (which include the more severe heights) were produced most often by local winds. On the other hand, variation in the frequency of waves from the south frequently were not consistent with the observed onshore winds from the south. In September, for example, there were few southern, onshore winds, but substantial wave action approaching the shore from directions south of the pier (Figure 22). This resulted from three tropical storms which developed well offshore to the south of the FRF and produced swell from that direction.

81. Overall, waves approached from south of the pier 5 percent more frequently during 1981 than during 1980. Despite similar seasonal tendencies for northerly waves in January through March and October through December and southerly waves for April through September, monthly variations of northerly and southerly directions were large throughout the years.

82. Differences are emphasized by the resultant vector wave height magnitudes and directions tabulated below. These resultants were computed by vector-averaging the daily wave height and direction vectors.

| <u>Season</u> | <u>Resultant Magnitude, m</u> | | <u>Resultant Direction Ref True North</u> | |
|------------------|-----------------------------------|-------------|---|-------------|
| | <u>1981</u> | <u>1980</u> | <u>1981</u> | <u>1980</u> |
| January-March | 1.0 | 0.9 | 66 | 52 |
| April-June | 0.6 | 0.6 | 78 | 70 |
| July-September | 0.7 | 0.6 | 70 | 75 |
| October-December | 1.1 | 0.9 | 61 | 46 |

83. During January through June 1981, more waves arrived from the south than during the same period in 1980; on the other hand, during July through September 1981, slightly more arrived from the north. From October through

Figure 22. September 1981 wind and wave directional distributions

December, the resultant distribution between north and south was approximately the same for both years, but the angles relative to the pier during 1981 were more nearly shore normal.

Current Data

84. Surface current measurements were made daily at about 0700 EST by timing the movement of dye patches at three locations: (a) the seaward end of the FRF pier, (b) the midsurf zone position under the pier, and (c) along the beach 500 m updrift of the pier. Results of these measurements are given in Table 7 and Figures 23, 24, and 25. Since nearshore surface currents are highly dependent upon wind speed and direction and wave breaker angle, there is significant variability between the mean values for these locations, (Figure 26). At the seaward end of the pier, wind direction is more likely to control the prevailing longshore current direction; whereas in the surf zone, the breaker angle tends to dominate.

BEACH (500M UP DRIFT)

Figure 25. 1981 longshore surface current speed and direction 500 m updrift of FRF pier

Figure 26. Monthly mean surface longshore current speed and direction at FRF for 1981

85. At the seaward end of the pier, the 1981 annual average current speed was 12 cm/sec southward, which agrees with the longer term average. Monthly means (Table 7 and Figure 26) show that strong southerly flows occurred during October and November 1981, which reflects the above-average incidence of northeasters during the period. This contrasts markedly with the 4-year average indicating maximum speeds in February and March. With the exception of April, all pier end mean monthly flows were to the south.

86. Both surf zone stations showed a general pattern of strong southward flow during the winter (Figure 26) and northerly flows during the summer when waves frequently approached from the south. February, however, was exceptional in the sense that currents were northward at both stations, with a southward minimum at the pier end.

87. The Mariner's Weather Log (NOAA/National Oceanographic Data Center 1981) states "the monthly mean sea-level pressure pattern was vastly different from climatology." High-pressure systems were unusually prevalent for February, off the east coast of the United States, accounting for the greater frequency of southerly winds.

88. Because of seasonally reversing longshore current patterns at surf zone locations, the annual resultant longshore current speeds were less in the surf than at the pier end; i.e., 6 cm/sec at the pier midsurf zone and only 3 cm/sec along the updrift beach. Other differences include an indication that individual current speeds were generally greater at the pier mid-surf zone than at the other two locations and that, occasionally, mean monthly currents in the surf zone were oppositely directed at the pier and the updrift beach.

89. On four occasions during 1981 (see tabulation below), the surface current speed exceeded 150 cm/sec. In each case, the currents were southwesterly directed and coincident with strong winds and high seas nearshore.

Tide and Water Level Data

90. Tide height values and water levels due to predominantly astronomical forces of the Sun and Moon are discussed first in this section, followed by a discussion of the extreme water levels which were particularly influenced by meteorological conditions. All tide heights are referenced to the local NGVD of 1929, unless otherwise specified. Appendix D contains hourly water level data for storm dates during 1981. Monthly and annual tide statistics for 1981 are shown in Table 8, with previous years' means and extremes included at the bottom for comparison. Tides at the FRF are semidiurnal, and the mean tide range for 1981 was 101 cm. MSL, the average of all tide heights during the year, was +9 cm. MHW was +59 cm, and MLW was -42 cm. The mean tide statistics for 1981 were very nearly the same as those for previous years.

* All elevations refer to 1929 NGVD.

** Explanation of abbreviations: MHW = mean high water; MTL = mean tide level; MSL = mean sea level; MLW = mean low water; MR = mean range; EH = extreme high water; and EL = extreme low water.

91. Mean and extreme monthly tide levels (Figure 27) show a 5- to 6-month periodicity; this phenomenon is due in part to the inclination of the Sun, a long-period astronomical tide constituent which has a periodicity of approximately 6 months. Additionally, astronomical forces with annual periodicity and the seasonal oscillation of the specific volume of sea water as a function of temperature, called the Steric effect, may explain the observed periodicity in the data (Pattullo et al. 1955). Strong offshore winds during most of April 1981 may in part explain its anomalously low water level statistics.

92. Although the annual statistics were nearly the same, hourly, daily high, and daily low tide height distributions for 1981 versus 1980 (Figure 28) reveal that during 1981 the high tides which occur infrequently--e.g., less than 2 percent of the time--were higher than those of the previous year. These extreme water levels were associated with meteorological events which coincided with spring tides. For comparison, during 1979 and 1980, 1 percent of the hourly tide heights exceeded 80 cm, while in 1981, 1 percent exceeded 90 cm. On four occasions during 1981, the water level exceeded the highest water level previously recorded since 1979. The numerous extreme water levels during the year, with the associated wave conditions and coincident tidal stages, are tabulated below:

| Date | Extreme High Water Level, cm | Wave Height, m | Comments |
|--------|---------------------------------|----------------|--|
| 4 May | 115 | 2.7 | Monthly spring tide |
| 30 Jun | 126 | 1.8 | Monthly spring tide |
| 20 Aug | 140 | 3.1 | Tropical Storm Dennis |
| 13 Oct | 125 | 2.6 | Perigean spring tide |
| 13 Nov | 149 | 3.5 | Perigean spring tide coincident with severe northeaster storm |
| 11 Dec | 113 | 1.0 | Proxigean* spring tide |

* Explained below.

93. Wood (1978) discusses perigee-syzygy and the occurrence of coastal flooding (when coincident with strong and persistent onshore winds) associated with the reduced lunar distances and solar-lunar alignment during perigean spring tides. Wood attributes the high water levels to the reinforcing effect that the alignment of the Sun's and Moon's gravitational forces have on the

Figure 27. 1981 monthly tidal means and extremes at seaward end of FRF pier

Figure 28. 1981 and 1980 tide height distributions

Earth and gives many examples of the effects of this phenomenon on coastal areas. Perigee-syzygy alignment, Wood states, can cause tidal flooding within a period of 1 to 3 days following (or in some few cases, a day or so preceding) the mean phase or epoch of the perigee-syzygy alignment. Approximately every 1 to 1-1/2 years, the Moon's orbit carries it exceptionally close to the Earth (Wood named this "proxigee"), creating especially amplified tides. The above tabulation identifies three occurrences during October through December 1981 of these strong astronomical forces, each coincident with large waves at the FRF.

94. In November, the perigean spring tide and a subtropical storm (northeaster) produced severe beach erosion, resulting in the destruction of a number of houses in the vicinity of the FRF. The water level rose to 149 cm, the highest water level recorded to date at the FRF.

Water Characteristics

Water temperature

95. Daily sea surface water temperatures at the seaward end of the FRF pier are presented in Figure 29. In 1981, as in 1980, large day-to-day temperature differences occurred in June, July, and August when frequent offshore winds blew warm surface water offshore, allowing upward and landward circulation of the much colder bottom water. Onshore winds reverse this circulation, piling up warm surface water against the shoreline, with a resulting seaward flow along the bottom.

96. The monthly mean sea surface temperatures for 1981 and 1980 presented in Figure 30 and seasonal distributions of temperatures for 1981 and 1980 data, combined in Figure 31, show the seasonal variability typical of this location. However, the winter minimum monthly mean was about 4 deg colder in 1981 than in 1980, and the July mean was about 4 deg warmer than in 1980. Overall, the 1981 annual mean was slightly warmer than the 1980 mean (Table 9).

Sea surface water visibility

97. Visibility in coastal nearshore waters depends on the amount of salts, soluble organic material, detritus, living organisms, and inorganic particles in the water. These dissolved and suspended materials change the absorption and attenuation characteristics of the water, which thus vary daily and throughout the year.

Figure 29. 1981 daily sea surface temperatures at seaward end of FRF pier

| Overall | 1.4 | 1.6 | 1.1 | 2.1 | 2.1 | 3.5 | 3.3 | 2.4 | 2.1 | 1.2 | 0.9 | 0.9 | 2.0 |
| <u>Mean Sea Surface Water Density, g/cm³</u> | | | | | | | | | | | | | |
| 1981 | 1.0252 | 1.0250 | 1.0254 | 1.0264 | 1.0243 | 1.0231 | 1.0215 | 1.0220 | 1.0225 | 1.0235 | 1.0241 | 1.0250 | 1.0240 |

98. Daily water visibility values, measured at the seaward end of the pier are shown in Figure 32. In 1981, as in 1980, largest day-to-day visibility differences occurred during the summer months, since the pattern of off-shore and onshore winds that produced major temperature differences also controlled the visibility. The warm surface water is usually quite clear, while the cooler bottom water contains large concentrations of suspended matter.

99. Figure 33, the distribution of surface water visibility for 1981 and 1980, shows that the 1981 values were much lower than those for 1980. 1981 and 1980 data combined indicated that 50 percent of the time the visibility was greater than 1 m and that 10 percent of the time visibility exceeded 3.5 m. Table 9 gives a summary of the water visibility data. Monthly mean visibility values for 1981 (Figure 34) and the seasonal distribution of visibility for the combined 1980 and 1981 data (Figure 35) show the seasonal variability typical at the FRF: higher values in the summer than during the remainder of the year.

Surface water density

100. Although there was considerable scatter in 1981 surface water density values (Figure 36), monthly mean values generally show an inverse dependence on water temperature (Figures 37 and 30). This pattern may be affected by rainfall; however, large amounts of rain occurred in July and August when density values were at a minimum (Figure 38 and Table 9). No density data were collected during 1980.

Survey Data

101. Waves and currents interacting with the beach and nearshore cause increases and decreases in the amount of sediment as a result of longshore transport, movement of the bar(s) on- or offshore, and the exchange of sediment between the beach and nearshore bottom. These changes can occur very rapidly, in response to a storm, or slowly as a result of seasonal variations in wave and current conditions.

102. In this section, time histories of bottom elevations at selected locations along the pier and contour diagrams of the bathymetry from the dune to 1,000 m offshore for a 1,000-m distance along the beach (centered at the pier) are presented.

Figure 36. 1981 daily sea surface densities

Figure 37. 1981 monthly and annual mean sea surface densities

Figure 38. 1981 seasonal and annual distribution of surface water density

History of bottom elevation

103. A history of the bottom elevations taken at the Baylor wave gage, pier end tide gage, and selected other locations along the pier is useful for

Figure 39. 1981 Maximum vertical variation of ocean bottom under FRF pier

interpretation of data. Variations of elevation under the pier are due to natural beach processes (such as profile changes due to bar movement), as well as to scour due to the interaction of the pier piles with waves and currents. Figure 39 shows the maximum vertical variation for 1981 as a function of depth. The most active areas were landward of 400 m due to a very mobile nearshore bar. Variations in the scour hole at the seaward end of the pier approached 2 m.

Bathymetry

104. Beginning in July and at approximately monthly intervals thereafter, the bathymetry adjacent to the FRF pier was surveyed. Contour diagrams based on the data for each survey are contained in Appendix C.

105. The scour resulting from the interaction of the pier with waves and currents produced a long, shallow trough under the pier (Figure 40). The trough, generally 100 to 200 m wide and extending slightly past the seaward end of the pier, changed depth, width, and symmetry in response to changing wave conditions.

106. Just inshore of the seaward end of the pier, the trough deepened into a large scour hole (Figure 41). During storms such as that on 13-16 November, this hole tended to deepen and expand in a downdrift direction (Figure 42). A more detailed description of the interaction of the pier with waves and currents and the effect on the bottom can be found in Miller, Birkemeier, and Dewall (1983).

107. The largest changes in the bathymetry during 1981 occurred during the November storm, when a large quantity of sediment moved from the north side to the south side of the pier (Figure 43). In general, the response of the

bottom to 3 days of waves from the northeast with H_m in excess of 3 m was a 75-m seaward movement of the nearshore bar. At the pier, the scour hole deepened to -9.8 m, its greatest depth since the pier was constructed.

Sediment Data

108. A summary of the 15 October sediment survey at the FRF is presented in Figure 44 and Table 10; sediment size distribution across one profile as a function of distance from a reference baseline is provided. Between the beach face and the nearshore trough (110 to 160 m from the baseline), sand sizes were coarse and poorly sorted, with standard deviations greater than 1.1 phi. On the dune and seaward of the nearshore trough (>160 m), sizes were better sorted and finer, although a clearly bimodal distribution occurred on the bar crest and seaward flank locations (i.e., 216 and 254 m from the baseline).

Photography

109. Two sets of photographic data were used to document nearshore and beach conditions in the vicinity of the FRF in 1981. Daily 35mm transparencies were taken of the beach from the pier looking both north and south (see sample in Figure 45). Aerial photographic missions were also flown on the flight lines and dates indicated in Table 11, usually at a scale of 1:12,000. Figure 46 is a sample of this imagery obtained on 24 March 1981.

APPENDIX A: WAVERIDER BUOY MAINTENANCE AND CALIBRATION INFORMATION

1. This appendix presents the maintenance and calibration required for the Waverider buoy gages.

2. Datawell recommends the Waverider buoys be cleaned and new batteries installed at least once every 9 months. The buoys were replaced on a number of occasions during the year, as listed in the gage histories in Appendix B. Considerable biological growth occurs during the summer months when the water temperature is above 10° C. Antifoulant paint and at least one cleaning and painting during the summer reduce the fouling problem.

3. The buoys were calibrated at the National Oceanic and Atmospheric Administration (NOAA) Engineering Support Office, Ocean Wave Instrument Facility (Ribe 1981).* Ribe presents the following three correction factors for use to increase wave measurement accuracy: (a) the Datawell-predicted decrease in electronic sensitivity as a function of oscillation period, (b) a difference error based on deviations from (a) found during NOAA's calibrations, and (c) a temperature-dependent adjustment of the sensitivity due to an unknown chemical reaction in the conducting fluid surrounding the Waverider accelerometer. These three corrections and their applications are discussed below.

Datawell-predicted Decrease in Sensitivity (DW)

4. Waverider buoy sensitivity /A/ for the buoy electronics decreases with increasing period T of sinusoidal vertical motion according to Datawell as follows:

$$/A/ = \frac{1}{\left[1 + \left(\frac{T}{T_o} \right)^4 \right]^{1/2}} \quad (1)$$

where $T_o = 30.8$ sec is a characteristic period provided by Datawell. This sensitivity decrease results in amplitude errors of less than 3 percent for oscillation (wave) periods less than 15 sec. Figures A1 through A4 present

* References cited in this appendix are included in the References at the end of the main text.

curves for $(DW) = /A/ - 1$, the Datawell-predicted sensitivity decrease error; the actual sensitivity does not decrease with period according to the Datawell relationship given in Equation 1.

Difference Error (d)

5. Ribe (1981) presents tables of the difference error based on a least-mean-squares-order polynomial in period T for a "best-estimate" difference error d between the Datawell-predicted decrease in sensitivity and that found from the actual buoy calibrations.

6. In Tables A1 through A9, DW (Datawell difference) and d are tabulated as functions of T for each buoy. Best accuracy is obtained by choosing the calibration values nearest in time to the date of the measurements.

Temperature-Related Error

7. It has been determined that for some unknown number of Waveriders the sensitivity is drifting downward, possibly since manufacture, on the average of about 1 percent per year. Sensitivity loss from some unknown chemical reaction is related to increases in electrical conductivity of the fluid surrounding the accelerometer. This drift is identified from successive calibrations over a period of years.

8. Recently, Datawell has introduced an improved modulator printed-circuit board for bringing calibrations within specification and for preventing further decreases in sensitivity. This modification has been made for buoy 66968, so the temperature-related error correction need not be applied. For all the other buoys--e.g., 66967, 66969, and 66977--it is recommended that the correction be used. Datawell has provided curves for correction of calibration and buoy temperature when the buoy is measuring waves in the ocean. The NOAA Engineering Support Office has, in turn, developed a table based on the Datawell curve which can be entered with the uncorrected difference error value d and the temperature of the water during the time of buoy operation to determine the difference error correction (Table A10). The difference error correction is added to d to obtain the corrected difference error, D . For temperatures during buoy operation greater than the buoy temperature during calibration (i.e., 22.4° C), no correction is necessary. Water temperature values may best be determined from Table 9 in the section entitled Water Characteristics in the main text of this report or from the FRF Monthly Preliminary Data Summaries (see References).

9. Since these error corrections are oscillation period dependent, their application requires that the wave data be decomposed into amplitude coefficients or variance-spectrum coefficients for each frequency or period. A less accurate but also less complicated procedure would be to apply a single correction to the wave height H_{m_0} based on the peak spectral wave period and an average water temperature estimate. For correction of amplitudes or derived parameters linearly related to amplitude, a correction factor $F(T)$ can be obtained from the sum of the Datawell DW and temperature corrected difference error D using

$$F(T) = \frac{1}{1 + (DW + D)} \quad (2)$$

Table A10

* Based on a figure provided by Datawell.

which can be applied by multiplying the uncorrected amplitude by $F(T)$ for T equal to the peak spectral wave period. For correction of parameters related to the square of the amplitude--i.e., total energy or variance spectrum coefficients--the following should be used:

$$[F(T)]^2 = \left[\frac{1}{1 + (DW + D)} \right]^2 \quad (3)$$

10. To apply the correction, first the difference error between the Datawell predicted error and the error measured during calibration are determined. This difference error is then adjusted for the temperature-dependent increase in electrical conductivity before the Datawell predicted difference error and the corrected difference error are summed. Finally, the decrease in sensitivity (based on the wave period) is computed by adding 1 to the sum.

11. To demonstrate the use of the calibration results, the Waverider located 3 km from shore recorded a wave height H_{m_0} of 4.1 m and wave period

T_p of 14 sec on 13 November 1981. Table A2 of calibration results for 18 February 1981 (buoy 66967) gives a difference error d for 14 sec which is -0.0779. From Part V the water temperature is estimated to be 12° C. Entering Table 10 with the difference error -0.08 and water temperature 12°C, the correction is 0.029. This is added to the uncorrected difference error d to obtain the corrected difference error D : $-0.0489 = -0.0779 + 0.029$. The corrected difference error ($D = -0.0489$) is added to the Datawell predicted difference error ($DW = -0.0220$; see Table A2 for $T_p = 14$ sec), e.g., $-0.0709 = -0.0489 + (-0.0220)$, and the sensitivity is computed by adding 1, or $0.9291 = 1 + (-0.0709)$.

12. This sensitivity is used to correct amplitudes and variance spectra coefficients for a 14-sec period.

Corrected amplitude = Uncorrected amplitude times $F(t)$, or

$$\frac{4.1m}{0.9291} = 4.4 \quad (7\% \text{ increase})$$

and the corrected variance coefficient =

$$\frac{\text{Uncorrected Variance Coefficient}}{(0.9291)^2}$$

13. In general, the wave statistics errors are near 5 percent for wave periods less than 12 sec (12 sec is equal to the annual mean plus 1 standard deviation wave period). Errors of this magnitude are generally tolerable for most engineering applications, although it is worthwhile to know the error bounds for some design considerations. When investigating coastal phenomena involving a very long period swell of 15 sec or greater, such as surf beats and sediment accretion due to swell waves, these corrections will produce significant increases in the magnitudes of the wave parameters. Therefore, it is recommended that the corrections be used.

APPENDIX B: WAVE DATA

Wave data are summarized in the following forms:

- a. Gage histories. Tables B1, B10, B19, and B28 include information about the gage, its installation, and major interruptions in the data collection. Short interruptions in the operational status of the gage are not mentioned.
- b. Time histories. All wave height H_m and peak spectral wave period T_p values are plotted as functions of the time throughout the year (Figures B1, B2, B14, B15, B22, B23, B30, and B31). So that the sequence of the data can be followed easily, solid lines connect consecutive data points for times when there is a gap of fewer than 24 hr between observations.
- c. Annual; seasonal; and monthly maxima, mean, and standard deviations of wave height and peak period. Mean H_m and standard deviation, mean T_p and standard deviation, and the extreme H_m for 1981 and for 1980 plus 1981 are listed in Tables B2, B3, B11, B12, B20, B21, B29, and B30. Also included is the total number of observations obtained. At four observations per day, the maximum number of observations per month (based on a 30-day period) is 120.
- d. Extreme, mean, and standard deviations of wave height and mean and standard deviations of peak period. The data presented in the tables described above are also graphed (Figures B3, B4, B16, B17, B24, B25, B32, and B33) for each month and for the year for 1981 and for 1980 plus 1981. Standard deviations are presented as vertical bars originating at the mean value and extending to the mean plus one standard deviation value. The extreme values are plotted above. No extreme period values are presented.
- e. Joint distribution functions of wave height versus peak period. Joint distribution tables for 1981 and for 1980 plus 1981 are tabulated for each year and season (Tables B4, B6, B13, B15, B22, B24, B31, and B33) and for each month (Tables B5, B7, B14, B16, B23, B25, B32, and B34). Each table gives the frequency (in parts per 1,000) for which H_m and T_p were within the specified intervals; these values can be converted to percent by dividing by 10. Marginal totals are also included. The row labeled "Total" gives the total number of observations out of 1,000 which fell within each specified period interval. The column "Total" gives the number of observations out of 1,000 which fell within each specified height interval.
- f. Cumulative distributions of wave height. For each gage, H_m distributions are plotted in cumulative form (Figures B5, B6, B18, B19, B26, B27, B34, and B35).

- g. Peak spectral wave period distributions. For each gage, T_p distributions are presented as annual and seasonal histograms for 1981 and for 1980 plus 1981 and monthly histograms for 1981 alone are presented (Figures B7, B8, B9, B20, B21, B28, B29, B36, and B37).
- h. Persistence of wave heights. Tables B8, B9, B17, B18, B26, B27, B35, and B36 show the number of times throughout 1981 and 1980 plus 1981 that the specified wave height was equaled or exceeded at least once during each day of the duration (consecutive days) indicated. For example, for gage 625 (pier-end Baylor), wave heights equaled or exceeded 0.5 m 26 times for at least 1 day, 25 times for at least 2 days, 20 times for at least 3 days, 17 times for at least 4 days, etc. Therefore, on one occasion one would expect the height to have equaled or exceeded 0.5 m for 1 day exactly, on five occasions for 2 days, on three occasions for 3 days, on two occasions for 4 days, etc. Note that the height exceeded 1 m 41 times for 1 day or longer, while heights exceeded 0.5 m only 26 times for this same duration. This occurred because the longer durations of lower waves may be interspersed with shorter, but more frequent, intervals of higher waves. For example, the one time that wave heights exceeded 0.5 m for 55 days may represent four or five times that the height exceeded 1 m.
- i. Wave roses. Wave roses showing the distribution of wave approach angles for gage 625 (pier-end Baylor) are presented for each month of 1981 and annually, seasonally, and monthly for 1980 plus 1981 (Figures B10, B11, and B12). The angles shown are referenced to true North. The FRF pier axis is oriented 69°58' east of true North. Northerly wave angles (e.g., those of less than 70 deg) generally produce southward currents, while southerly wave angles, which are greater than 70 deg, produce northward currents.
- j. Spectra. Sample spectra for gage 625 (pier-end Baylor) for days when wave heights exceeded 2 m at gage 625 are presented in Figure B13. The plots show energy density as a function of wave frequency every 6 hr throughout the day.

Table B1

1981 Wave Gage History for Gage 625

| Type of Gage and Location | Coordinates | Beginning of Proper Operation | End of Proper Operation | Explanation | Gage Length m | Gage Range m, MSL | Water Depth m, MSL | Distance from Baseline m |
|--|----------------------------|-------------------------------------|-------------------------------|--|---------------------|-------------------------|--------------------------|--------------------------------|

APPENDIX C: SURVEY DATA

Time History Graphs of Bottom Elevations (Figures C1 and C2)

1. Each graph shows how the bottom elevation varied throughout the year. The vertical datum is National Geodetic Vertical Datum (NGVD), and the horizontal datum is the monumentation baseline.

Contour Diagrams (Figures C3 through C7)

2. Contour diagrams were constructed from the bathymetric survey data. The profile lines surveyed are identified on each diagram. Contours are in half meters referenced to NGVD.

APPENDIX D: STORM DATA

1. This appendix presents a summary of storm data for 1981 collected hourly during times when H_{m_0} exceeded 2 m at gage 625, along with a brief explanation of the conditions causing the high waves (Appendix B contains wave spectra for gage 625 on dates when H_{m_0} exceeded 2 m). Storm periods are detailed in the following paragraphs.

21 January (Figure D1)

2. A low formed over Cape Hatteras, with NNE winds up to 15 m/sec producing wave heights up to 2.5 m on 21 January.

11 February (Figure D2)

3. A high-pressure system, originating over the central US moved east arriving offshore of New England on 10 February. Onshore winds persisted throughout 11 February, resulting in wave heights in excess of 2 m during the day.

14 February (Figure D3)

4. A high-pressure system developed on 13 February and remained stationary over the coast of Delaware and Maryland, producing onshore winds and storm waves during 14 February.

23-24 February (Figure D4)

5. A low-pressure system centered over eastern Maryland moved eastward into the Atlantic producing SSE winds on 19 and 20 February; this system continued to affect the coastal wave conditions as it moved offshore. A huge new low developed over Indiana on 22 and 23 February. These two systems resulted in SSE winds of speeds up to 6.7 m/sec and produced 2.8-m, 17-sec waves on 23 February along the coast.

8-9 March (Figure D5)

6. A low-pressure system formed west of Norfolk, Va., on 5 March, with winds of 11 m/sec from the SSE. The low moved well offshore and deepened into a major storm, producing 2.5-m waves on 9 March.

23-24 March (Figure D6)

7. A low-pressure system crossed Cape Hatteras moving NE on 23 March, causing NNE winds up to 14 m/sec. The low continued eastward through 24 March, resulting in wave heights of over 2.5 m.

13-14 April (Figure D7)

8. A Canadian high-pressure system pushed a cold front past the FRF on 13 April. The high moved south along the New England coast throughout 14 April, resulting in high waves at the FRF.

4 May (Figure D8)

9. A low-pressure system off the Delaware coast coupled with a high over western Pennsylvania resulted in northerly winds along the central eastern seaboard causing storm waves at the FRF.

8 May (Figure D9)

10. A low which formed off the New England coast on 3 May produced north winds of up to 6 m/sec and advanced slowly to the SW with ENE winds increasing to 11.8 m/sec.

23 August (Figure D10)

11. Preceded by a large rain umbrella, Tropical Storm Dennis began its northward journey along the southeastern coast early on 19 August and had by the morning of 20 August passed Cape Hatteras, N. C., heading into the north Atlantic where it would quickly intensify to hurricane strength. The

maximum wave height was 3.52 m at 0900 EST on 20 August, with the highest sustained winds of 18.13 m/sec recorded at 0800 EST on 20 August. Waves of 2 m and higher were recorded for 68 consecutive hours (19 August, 1700 hours, through 22 August, 1200 hours). A total of 128 mm of precipitation fell during the storm, with 115 mm falling on 20 August. A large amount of erosion occurred along most of the profile line from the foreshore to the storm bar which was flattened and moved 50 m seaward. Seaward of the storm bar up to 0.7 m of sediment was removed.

3-5 September (Figure D11)

12. Tropical Cyclone Emily developed off Bermuda and curved NE. Combined with a large high-pressure system to the north, Emily produced large swells and high tides. Northeast winds prevailed for two days, reaching 8.7 m/sec and producing 2.8-m waves along the North Carolina coastline.

12-16 October (Figure 12)

13. A low-pressure system moving ENE off Georgia combined with a very large high-pressure system to the north and produced NNE winds up to 14.4 m/sec, with wave heights up to 2.7 m.

30 October-1 November (Figure D13)

14. A very large high-pressure system centered above northeastern Canada produced strong NNE winds for 30 October, with peaks up to 13.3 m/sec.

12-15 November (Figure D14)

15. A combination of a low-pressure system off the North Carolina coast and the syzygy-perigean alignment of the Sun, Moon, and Earth resulted in high waves and water levels with extensive beach changes at the FRF. A cold front which developed in the southwest part of Canada during the weekend of 7 November moved across the United States and passed the FRF (Outer Banks) on Tuesday, 10 November. A low-pressure system, centered in the Gulf of Mexico at that time, moved across Florida on 11 November and up the east coast.

On 12 November, the low stalled off the North Carolina/Virginia coast where it remained through 14 November before moving to the north. Wave heights measured at the nearshore Waverider (gage No. 610) were in excess of 3 m from 12-14 November, while water levels remained almost continuously above the mean water level, with an extreme of 1.49 m above the local mean sea level. After the storm, major seaward shifts of all contour lines between +3 m and -7 m were apparent, with a maximum shift of 80 m occurring on the -4 m contour at the 300-m position on the baseline. The ever-present hole at the end of the FRF pier deepened considerably from -8 m to almost -10 m and expanded to the southwest about 50 m. In addition, a 4-m-deep trench, 75 m wide and extending 325 m north and 75 m south of the pier, was created. Survey data collected on a profile line 516 m south of the pier show some dramatic changes to the profile. On the foreshore (70 m to 110 m), a volume loss of -49 cu m/m occurred between elevations of +3.5 m to -0.5 m. A large portion of this (44 cu m/m) was apparently deposited in the nearshore (i.e., the 110- to 180-m) portion of the profile. A 78-m seaward shift of the storm bar resulted in a net loss of 10 cu m/m, with a net average volume loss to the profile of -15 cu m/m.

25-26 November (Figure D15)

16. A low formed over South Carolina on 24 November and moved north and deepened in the vicinity of Cape Hatteras on 25 November. High waves persisted during both days.

5-6 December (Figure D16)

17. A low-pressure system formed over North Carolina and moved offshore, producing winds 6 to 12 m/sec and 2.6-m wave heights.
